*"One man's
crappy software
is another man's
full-time job. "*

The POSIX IEEE standard

eng.wikipedia.org

POSIX Threads, usually referred to as PThreads, is an execution model that exists independently from a language, as well as a parallel execution model. It allows a program to control multiple different flows of work that overlap in time.

- › Threading API
- › Single process
- › Shared memory space

The POSIX IEEE standard

- › Specifies an **operating system interface similar to most UNIX systems**
 - It extends the C language with primitives that allows the specification of the concurrency

- › POSIX distinguishes between the terms process and thread
 - "A **process** is an address space with one or more threads executing"
 - "A **thread** is a single flow of control within a process (a unit of execution)"

- › Every process has at least one thread
 - the "`main()`" (aka "**master**") thread; its termination ends the process
 - All the threads **share** the same address space, and have a **private** stack

Thread body

- › A (P)thread is identified by a C function, called body:

```
void *my_pthread_fn(void *arg)
{
    // Thread body
}
```

- › A thread starts with the first instruction of its body
- › The threads ends when the body function ends
 - It's not the only way a thread can die

Thread creation

- › Thread can be created using the primitive

pthread.h

```
typedef unsigned int pthread_t;

int pthread_create ( pthread_t *ID,
                    pthread_attr_t *attr,
                    void *(*body)(void *),
                    void * arg
                    );
```

- › pthread_t is the type that contains the thread ID
- › pthread_attr_t is the type that contains the parameters of the thread
- › arg is the argument passed to the thread body when it starts

Thread attributes

- › Thread attributes specifies the characteristics of a thread
 - We won't see this; leave empty
- › Attributes must be initialized and destroyed - **always**

pthread.h

```
int pthread_attr_init(pthread_attr_t *attr);  
  
int pthread_attr_destroy(pthread_attr_t *attr);
```

Thread termination

- › A thread can terminate itself calling

pthread.h

```
void pthread_exit(void *retval);
```

- › When the thread body ends after the last “}”, `pthread_exit()` is called implicitly
- › Exception: when `main()` terminates, `exit()` is called implicitly

Thread IDs

- › Each thread has a unique ID

pthread.h

```
pthread_t pthread_self(void);
```

- › The thread ID of the current thread can be obtained using

pthread.h

```
int pthread_equal( pthread_t thread1,  
                  pthread_t thread2 );
```

- › Two thread IDs can be compared using

Joining a thread

- › A thread can wait the termination of another thread using

pthread.h

```
int pthread_join ( pthread_t th,  
                  void **thread_return);
```

- › It gets the return value of the thread or `PTHREAD_CANCELED` if the thread has been killed
- › By default, every thread **must** be joined
 - The join frees all the internal resources
 - Stack, registers, and so on

Example

Let's
code!

- › Filename: `ex_create.c`
- › The demo explains how to create a thread
 - the `main()` thread creates another thread (called `body()`)
 - the `body()` thread checks the thread ids using `pthread_equal()` and then ends
 - the `main()` thread joins the `body()` thread
- › When compiling under gcc & GNU/Linux, remember
 - the `-lpthread` option!
 - to add `#include "pthread.h"`

› Credits to PJ

Semaphores

Semaphores

A semaphore is a counter managed with a set of primitives

It is used for

- › Synchronization
- › Mutual exclusion

POSIX Semaphores can be

- › Unnamed (local to a process)
- › Named (shared between processes through a file descriptor – we won't see them)

Unnamed semaphores

Operations permitted:

- › initialization /destruction
- › blocking wait / nonblocking wait
 - counter decrement
- › post
 - counter increment
- › counter reading
 - simply returns the counter

Initializing a semaphore

- › The `sem_t` type contains all the semaphore data structures

```
int sem_init(sem_t *sem, int pshared, unsigned int value);
```

- `pshared` is 0 if `sem` is not shared between processes

```
int sem_destroy(sem_t *sem)
```

- It destroys the `sem` semaphore

Semaphore waits

```
int sem_wait(sem_t *sem);  
int sem_trywait(sem_t *sem);
```

- › Under the hood..
- › If the counter is greater than 0 the thread does not block
 - `sem_trywait` never blocks

Other semaphore primitives

```
int sem_post(sem_t *sem);
```

- It increments the semaphore counter
- It unblocks a waiting thread

```
int sem_getvalue(sem_t *sem, int *val);
```

- It simply returns the semaphore counter

Example

Let's
code!

- › Filename: `ex_sem.c`
- › In this example, semaphores are used to implement mutual exclusion in the output of a character in the console.

PThreads scheduling

Scheduling algorithms

- › The POSIX standard specifies in `sched.h` *at least* two scheduling strategies which can be used, identified by the symbols `SCHED_FIFO` and `SCHED_RR`
 - Other scheduling policies may be supported by each particular implementation, under the symbol `SCHED_OTHER`

POSIX specifies a Fixed Priority scheduler with at least 32 priorities (0 to 31)

- › Every priority corresponds to a queue, where all the threads with the same priority are inserted
- › The first ready thread in the highest non-empty priority queue is selected for scheduling and becomes the running thread

POSIX and priorities

thread priorities can be specified at creation time into the thread attributes

```
int pthread_attr_setschedpolicy  
    (pthread_attr_t *a, int policy);
```

› policy can be SCHED_RR, SCHED_FIFO or SCHED_OTHER

```
int pthread_attr_setschedparam  
    (pthread_attr_t *attr,  
     const struct sched_param *param);
```

› The priority field is param.sched_priority

Real-Time and UNIX

- › UNIX systems usually schedule all its threads at low priorities
- › When a RT thread is created, it always preempts all the other applications (i.e. the X server, and all the other demons)
- › For that reason,
 - real-time computations have to be limited
 - **only root** can use the real-time priorities

Example

Let's
code!

- › Filename: `ex_rr.c`
- › The demo explains the behavior of the RT priorities and of the other policies
- › The `main()` thread creates a high priority thread that activates a low priority thread and two medium priority threads
- › The medium priority threads are scheduled with policies `SCHED_RR` and `SCHED_FIFO`
- › When compiling under gcc & GNU/Linux, remember
 - the `-lpthread` option!
 - to add `#include "pthread.h"`
- › Credits to PJ

How to run the examples

Let's
code!

› Download the Code/ folder from the course website

› Compile

```
$ gcc code.c -o code -lpthread
```

› Run (Unix/Linux)

```
$ ./code
```

› Run (Win/Cygwin)

```
$ ./code.exe
```
